

Stock Price Analysis Report

5-Year Historical Price Trend Review | July 2021 – July 2026

1,254 Trading days analyzed	+117% Total price growth	54% Green (up) days	65.3M shares Avg. daily volume
---------------------------------------	------------------------------------	-------------------------------	--

1. Dataset Overview

This report is based on 1,254 days of daily stock trading data, covering roughly five years from July 6, 2021 to July 2, 2026. For each trading day, the dataset recorded the opening price, closing price, the highest and lowest price reached, and the trading volume (how many shares changed hands).

The data arrived in good shape overall — there were no missing entries — but the price columns were stored as text (for example "\$308.63" instead of the number 308.63) because of the dollar sign. This meant the numbers couldn't be used for any calculations until they were cleaned.

2. Data Transformation Techniques Applied

- Removed dollar signs from the price columns and converted them into proper numbers so they could be used in calculations.
- Converted the date column from plain text into a true calendar date, which made it possible to sort the data chronologically and pull out the year, month, and day of the week for each entry.
- Sorted the entire dataset from the oldest trading day to the most recent, so trends read naturally from left to right.
- Checked for missing or broken values throughout the process — none were found, so no rows needed to be removed or filled in.

3. Trends Identified

The stock's average closing price rose steadily nearly every year across the period studied:

2021	2022	2023	2024	2025	2026
\$152.85	\$154.84	\$172.55	\$207.21	\$232.24	\$273.70

(2026 reflects only the first half of the year.) The price roughly doubled over the five years — from \$142.02 at the start of the dataset to \$308.63 at the end, a total gain of about 117%. The lowest closing price recorded was \$125.02 (January 2023), and the highest was \$315.20 (June 2026).

Trading activity was not steady — some days saw far more buying and selling than others. The busiest trading day was September 20, 2024, with over 318 million shares traded, more than four times the typical day. Spikes like this usually line up with major news or company announcements and are worth investigating further if a deeper story is needed.

On a day-to-day basis, prices moved up slightly more often than they moved down: 54% of days closed higher than they opened. The single best day gained over 15% in one session (April 9, 2025), while the worst single day lost more than 9% (April 3, 2025) — a reminder that even a stock on a long-term upward path can have sharp, sudden swings.

4. Features Created

To make the raw prices easier to analyse, several new calculated columns were added:

- Daily Price Change & Daily % Change – how much the price moved, in dollars and in percentage terms, from the previous day.
- Daily Range – the gap between the day's highest and lowest price, a simple measure of how choppy that day was.
- 7-Day and 30-Day Moving Averages – a smoothed version of the price that filters out daily noise, making the underlying trend easier to see.
- Volatility (7-day) – how much the daily returns swung around over the past week, used as a simple risk indicator.
- Year, Month, and Day of the Week – pulled out of each date to allow grouping and comparison across time periods.
- Monthly Returns – the percentage gain or loss from the end of one month to the end of the next, useful for spotting seasonal patterns.

5. Key Insights from the Analysis

- The stock has been on a strong, multi-year uptrend, with average yearly prices climbing every single year in the dataset.
- Growth has accelerated in recent years — the jump from 2023 to 2024 and 2024 to 2025 was noticeably larger than earlier years, suggesting increasing investor interest or business momentum.
- Daily price swings, while usually modest (about 1.75% on an average day), can occasionally be extreme — the April 2025 dates show gains and losses of 9–15% within days of each other, which is unusually volatile even for this stock.
- Trading volume spikes tend to cluster around the same periods as the largest price swings, reinforcing that these were likely reactions to real news events rather than random noise.

6. Recommendations

Treat the April 2025 period as a case study — pulling news or earnings reports from that week would explain the extreme swings and could reveal a repeatable pattern (e.g., earnings reactions) worth tracking going forward.

- Use the 7-day and 30-day moving average lines, not the daily closing price alone, when judging the overall trend — daily prices are too noisy on their own to act on.
- Keep an eye on unusually high trading volume days going forward, since they've historically coincided with the sharpest price moves and can act as an early warning sign?
